Toward four-dimensional molecular orientation imaging

Patrick La Riviere, University of Chicago

with Talon Chandler (Uchicago), Hari Shroff, Min Guo (NIH), Rudolf Oldenbourg (MBL)

Goal: To capture a dynamic series of three-dimensional volumes of fluorescent molecules reporting both the position AND orientation of target molecules of interest (eg, actin).

We have added polarization filters to the excitation channels of a diSPIM dual-view light-sheet microscope

It captures four polarization-sensitive stacks from each of two orthogonal directions.

Physics and math implemented on a computer gives us this: spatially resolved images of major molecular orientation in each voxel.

seeing color in the visual world of multiple predators

Field + lab;

350-650nm range;

acquire natl light images

Derya Akkaynak

Some prelim results:

Tetra- can see more color than trichromat

*in some cases, tri- can see more than tetrachromat

Clouds, time of day, depth affect who sees color best

REMINDER: baby step- measuring retina only; no perception

there is a huge amount yet to learn about color perception

How different body shapes are generated during deuterotome evolution?

What is the

Epigenomics: ChIP-seq, ATACseq

3D Chromatin structure: 4C-seq, HiChiP, HiC

Functional studies in zebrafish/medaka/Xenopus
